Optimal Experimental Design for Non-Linear Models - springer

In the design of experiments, optimal designs (or optimum designs) are a class of experimental designs that are optimal with respect to some statistical criterion. The creation of this field of statistics has been credited to Danish statistician Kirstine Smith. In the design of experiments for estimating statistical models, optimal designs allow parameters to be estimated without bias and with minimum variance. A non-optimal design requires a greater number of experimental runs to estimate the p

Transverse or transectional design . This type of non-experimental research design is used to observe and record the data at a specific time and, by its very nature, unique. In this way, the analysis is focused on the effects of a phenomenon that occurs at a particular time.

Non-Experimental Research: Designs, Characteristics, Types ...

In this paper, we study optimal multi-period experimental design under the constraint that the treatment cannot be easily removed once implemented; for example, a government or firm might implement treatment in different geographies at different times, where the treatment cannot be easily removed due to practical constraints.

Hence, if determining the optimal experimental design is the only goal, the optimal or closed optimal experimental design can be determined without knowledge of σ P 2. Table 5 . LCI SNR of extreme cases and optimal experimental design at C U = 180 when C P , C O , C M = . 10 , 6 , 1 .

Optimal experimental design for event-related fMRI.

Optimal designs will not generate the best design points from some continuous region--that is too much to ask of the mathematics. Optimal designs will generate the best subset of points from a larger superset of candidate points. The user must specify this candidate set of points.

3.1.1 Naive experimental design and non-iterative algorithm results . We first compared results from the unchanged naive experimental design (such as used in []) to a non-iterative version of the optimal design algorithm described above, i.e., optimizing only the observation times (τ) or the input b^* . For each case, we considered a scenario with 27 experimental observation times of total ...

His main research topic is the optimal design of experiments. He has published a book as well as several methodological articles on the design and analysis of blocked and split-plot experiments. Other interests of his in this area include discrete choice experiments, model-robust designs, experimental design for non-linear models and for ...

Design and Analysis of Experiments with R

For a concave optimality criterion, an approximate design is optimal in the class of all normal- ized approximate designs if and only if all its directional derivatives are non-positive. This state- ment can be rewritten to the form of the so-called equivalence theorem.

In such cases, MBDoE (also known as Optimal Experimental Design) deals with the challenge of finding the experimental setup that minimizes the uncertainty on the parameter estimates of models that show a non-linear dependency on the parameters (Franceschini and Macchietto, 2008).

Quasi-experimental designs typically allow the researcher to control the assignment to the treatment condition but using some criterion other than random assignment (e.g., an eligibility cutoff mark). In some cases, the researcher may have control over assignment to treatment condition. Non-Experiment: the researcher cannot control, manipulate or alter the predictor variable or subjects, but instead, relies on interpretation, observation or interactions to come to a conclusion.

We demonstrate that the recently developed Optimal Uncertainty Quantification (OUQ) theory, combined with recent software enabling fast global solutions of constrained non-convex optimization problems, provides a methodology for rigorous model certification, validation, and optimal design under uncertainty. In particular, we show the utility of the OUQ approach to understanding the behavior of ...
