Clearly, when $e(k)$ is very small, the adaptive filter response is close to the response of the unknown system. In this case, the same input feeds both the adaptive filter and the unknown. If, for example, the unknown system is a modem, the input often represents white noise, and is a part of the sound you hear from your modem when you log in to your Internet service provider.

Finding the Optimal Filter Solution, W_{opt} , cont. yThe MSE, $C=E[(d(k)-\{X\}\{W\}^T)^2]$, is a quadratic function of the filter weights, $\{W\}$ yThere is a unique minimum of C corresponding to $W_{opt}(k)$ yThe minimum is found through differentiation: ySolve the above equation for $\{W\}_{opt}$ yIn real life, we don't have the luxury of the equation for $C \{0 \dots$

At this stage the least squares solution, obtained by minimizing the cost function $J = E\{e^2(n)\}$, gives a poor estimation of the solution of adaptive filtering problem because of the presence of noise in filter input. Casting adaptive filtering problem as total least squares problem can, however, restructure the poor estimation of solution under noisy input [10, 11].
